The Peripherals: input and output devices

Peripherals are the physical units attached to a computer and they consist of three types: input, output and storage devices. Input devices are the ones that enter the data to be processed afterwards, such as keyboard, mouse and microphone, while output devices show the results and bring the information to the user, like the monitor, the speakers and the printer. Storage devices store the data on the computer.

On the one hand, computer devices give you the tools to complete tasks, hold meetings and do your job properly, so your work becomes automatic. Another strong point is the quality and speed of sharing information and sending photos, and this is due to high-quality peripherals. They also make it possible to create graphic design, which helps small businesses build a good marketing strategy.

On the other hand, if a hacker infects your device with a virus, your hard disk can be compromised and your personal data can be lost forever .Security is the only area where our devices and their components still need to be improved. Another disadvantage is physical: typing with a bad hand position or holding the mouse incorrectly for hours can hurt our hands, wrists and posture.

To sum up, computer devices play a special role in our lives by automating small tasks so we can focus on harder ones. Personally, I think knowing their strong and weak points helps us use them properly and set clear rules.
